Installation	3
Install JAVA environment	3
Install Chrome	3
Install the Framework	3
Install GIExtenstion (Chrome Plugin)	3
Run the Software	4
Architecture	4
Angry Birds Extension	5
Al Agent	5
Proxy	5
S/C Communicating Port	5
Vision Module	6
Trajectory Module	7
The Naive Agent (standalone) – a demo	9
Naive Agent	9
Play the Naive Agent	9
Load the Game Window	9
Run the Naive Agent	9
Create your own Intelligent Agent	10
Screen Shot and Segment an image	10
Access the Game State	10
Trajectory Module	10
Execute Shooting Actions	10
Self-Manage mode	11
Auto-Arrange mode	11
Focus Point	
Compile using ANT	13

## Installation

## **Install JAVA environment**

The framework has been tested with the JAVA6 and above. To check your java version, you can enter java -version in your command window.

You can download java environment (JRE) from this link <a href="http://www.oracle.com/technetwork/java/javase/downloads/index.html">http://www.oracle.com/technetwork/java/javase/downloads/index.html</a>

### **Install Chrome**

Chrome can be obtained from <a href="http://www.google.com/intl/en/chrome/browser/">http://www.google.com/intl/en/chrome/browser/</a>

### **Install the Framework**

Unzip the software package (e.g. versionX.zip), assuming the directory of the software folder is ./angrybirds/

You will have the following files/folders:

- ♣ The external folder contains all necessary libraries.
- ♣ The src folder contains all source files
- The GIExtension folder: extension for interfacing with Chrome.
- ♣ The trapts file: The default trajectory file that will be used by the naive agent
- The setup.ini file: the file used to specify the focus\_point. (discussed in section <Other Issues>)

## **Install GIExtenstion (Chrome Plugin)**

- 1. Open Chrome
- 2. Go to: chrome://chrome/extensions/
- 3. Click the 'Developer mode' check box
- 4. Click the 'Load unpacked extension...' button
- 5. Browse for the 'GIExtension' folder (contains the 'manifest.json' file)

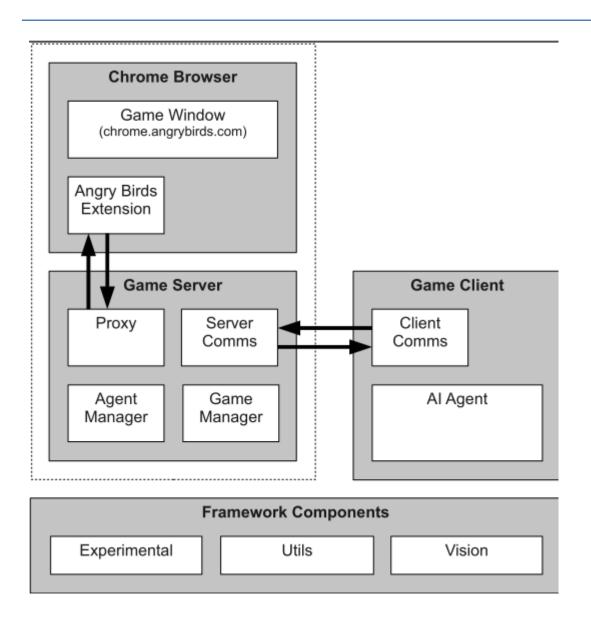

NOTE: if the screenshots are coming out as transparent PNG files do this:

- 1. Open Chrome
- 2. Go to: chrome://flags/
- 3. Find the option 'Disable WebGL' and enable it (i.e. enable the disabling of WebGL)

### **Run the Software**

There are two commands available through the command line. You can run the naive agent (see section Run the Naive Agent), view the segmentation of the game images in the real-time (see section Vision Module) and view the real-time trajectory output (see section Trajectory Module)

## Architecture

## **Angry Birds Extension**

The chrome plugin interacts with the chrome browser. It offers functionalities such as capturing game window, executing actions (e.g. move the mouse, click, and wheel to zoom). To install it, please see Install GIExtenstion (Chrome Plugin)

### **AI Agent**

An agent will use the vision module to analyze game scenarios and the trajectory module to plan on shots. Although the framework is written in java, the agent can be done in other languages such as c++, phython, etc.

## **Proxy**

The server interacts with the angry birds extension via the proxy module. The following are the proxy messages:

- CLICK: left click of the mouse
- DRAG: drag the cursor from one place to another
- SCREENSHOT: capture the current game window

The agent does not need to access the Proxy component.

## **S/C Communicating Port**

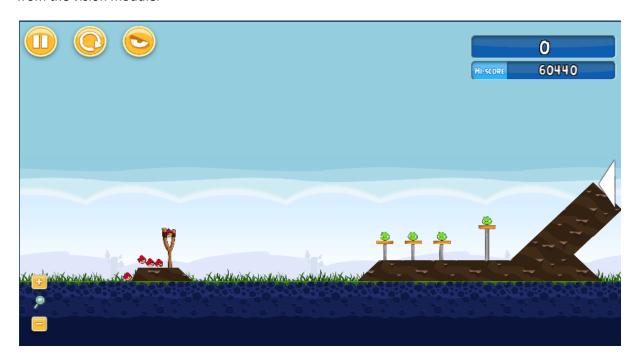

Server/Client Communicating Port receives messages from agents and sends back feedbacks after the server executed the required actions indicated by the messages. An agent is allowed to send the following messages and the messages are strings:

- LOAD LEVEL
- REQUEST SCORES
- SCREENSHOTS
- **EXECUTESHOTS**

The syntax of the messages will be provided when server/client mode is released

### **Vision Module**

The vision module will segment an image and captures the minimum bounding rectangles of essential objects in the image. (The *essential objects includes {"Red Bird", "Wood", "Trajectory", "Tap", "Pig", "Ice", "Stone", "Slingshot", "Blue Bird", "Yellow Bird"};)* The following is an illustration of the output from the vision module.

To show the real-time segmentation, you can type and execute the command in the command window under the software directory.

### java -jar ab1.0.jar -showSeg

## **Trajectory Module**

The Trajectory Module estimates the trajectory that a bird will follow given a particular release point (relative to the slingshot). We use a constant velocity for every shot within the same level and use the release point and slingshot location to determine the launch angle a. From these we can compute the initial horizontal and vertical velocities as  $v \cos(a)$  and  $v \sin(a)$ , respectively.

With the initial velocities in hand, we use Netwon's classical laws of physics to estimate the parabolic path that the bird will take. The predictTrajectory function in the Trajectory Module returns a list of points that the bird will follow given a certain release point. To facilitate planning shots, the Trajectory Module provides a function (called estimateLaunchPoint) to estimate the release point given a desired target (for example, the centre of one of the detected pigs). The function uses the following equation to calculate the launch angle

$$\theta = \arctan\left(\frac{v^2 \pm \sqrt{v^4 - g(gx^2 + 2yv^2)}}{gx}\right)$$

Where (x, y) are the normalised coordinates of the target point relative to the sling (using sling size as the scale), and the gravity g is assumed to be 1 unit. Two angles are obtained from this equation and the function returns two corresponding launch points in an ArrayList of Points.

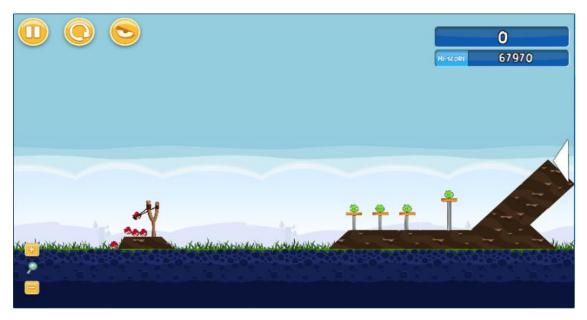

Note that when a shot is made, the actual launch angle a is always slightly different from the arctangent of the launch vector and the difference varies from level to level. Also, the normalised velocities are slight different between levels. The variation in angle and velocity are taken into account when predicting trajectories and estimating launch points. The trajectory module provides a method (adjustTrajectory) to adjust these two changes using information from a previous shot, so that the accuracy of the following shots is improved.

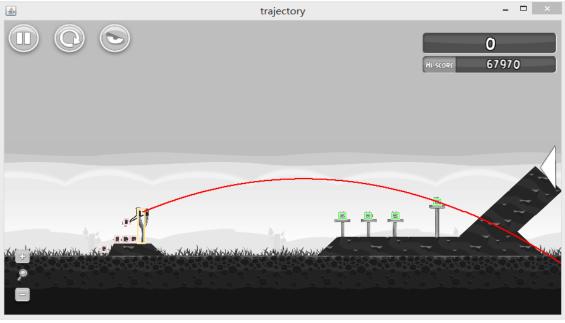

Also note that due to pixel level variations in the location of the slingshot and bird and effects due to scaling, the paths estimated by the Trajectory Module are only approximate. Agents should take this into account when planning their shots.

To show the real-time segmentation, you can type and execute the command in the command window under the software directory.

java -jar ab1.0.jar -showTraj

## The following is an example output

# The Naive Agent (standalone) - a demo

### **Naive Agent**

The naive agent is created to demonstrate how to construct an agent on the basis of the provided modules, namely, the chrome plugin, the vision module, and the trajectory module. The naive agent is called "naive" because it shoots bird directly to the pig without reasoning.

The code can be found in /src/ab/demo/NaiveAgent.java

## **Play the Naive Agent**

### **Load the Game Window**

To load the game window

- 1. Open Chrome
- 2. Maximize the browser window
- 3. enter "http://chrome.angrybirds.com/" in the address bar, then press enter
- 4. Select **SD** version, then click Play
- 5. Select the episode POACHED EGGS and stay at the level selection page.

(the level selection page)

Please keep the tab of the game activated. You do not need to keep the browser window in front of the screen. i.e. you can minimize the window after loading the game, but ensure the tab remains selected.

### **Run the Naive Agent**

Assuming the directory of the software is /angrybirds/versionX, to run the naive agent

- 1. Load the game in Chrome (see section Load the Game Window)
- 2. Open the shell.
- 3. Go to the software directory.

4. Execute the command java -jar ab1.0.jar -na [1-21] to invoke the naive agent, the naive agent will start from the level you specified. The initial level is 1 by default.

E.g. java -jar ab1.0.jar -na 2 will start the naive agent in the level 2.

## Create your own Intelligent Agent

### **Screen Shot and Segment an image**

It is very easy to make a screen shot and segment it. The following is a code fragment showing the process:

//capture Image
BufferedImage screenshot = doScreenShot();
// process image
Vision vision = new Vision(screenshot);
List<Rectangle> red\_birds = vision.findRedBirds();
List<Rectangle> blue\_birds = vision.findBlueBirds();
List<Rectangle> yellow\_birds = vision.findYellowBirds();
Please refer to /src/ab/vision/Vision.java for details

### **Access the Game State**

There are four main game states

- 1. "Won": a page shows the final grade and the stars you won.
- 2. "LOST": a big pig tells you lost
- 3. "PLAYING": the game is not finished
- 4. "LEVEL SELECTION": the level selection page.
- 5. "LOADING": the game is currently loading and a progress bar is showing on the page

Please refer to /src/ab/vision/GameStateExtractor.java for details

### **Trajectory Module**

Once you know your target, you need the trajectory module to plan on the shots. To get the set of estimated release points given a target, you can call the estimateLauchPoint(Rectangle, Point) method. This method requires a bounding box of the slingshot and the target point

```
//Initial a trajectory planner
TrajectoryPlanner tp = new TrajectoryPlanner();
//Get the estimated points
ArrayList<Point> pts = tp.estimateLaunchPoint(sling, tpt);
```

Please refer to /src/ab/planner/TrajectoryPlanner.java for details

### **Execute Shooting Actions**

You have two ways to shoot a sequence of birds. A SHOT contains six fields (x,y,dx,dy,t\_shot,t\_tap) The first four parameters specify a move from (x,y) to (dx,dy). T shot is the time at which a bird is

This work is licensed under Creative Commons Attribution-NonCommercial-ShareAlike 3.0 Unported License and can be accessed via https://github.com/aibirds/agent

supposed to be launched. T\_tap specifies the gap between the releasing time and the corresponding tapping time. Time are counted in milliseconds

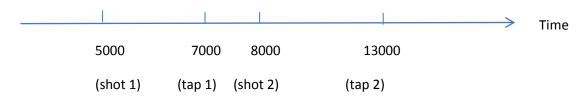

You can submit a list of shots to the server and the server will execute shooting accordingly.

#### Self-Manage mode

Let's say you want to shoot 2 birds and the following are corresponding shot instances:

- 1) Shot (x,y,dx,dy, 5000,2000);
- 2) Shot (x,y,dx,dy, 8000,5000);

You can pass the two shots via ClientShootCmd to the server, and the server will shoot the bird following the timeline below:

Note: t\_tap specifies the gap between the releasing the time and the corresponding tapping time. When you specify the shooting time, please beware that:

1) Avoid executing a shoot and tap actions at the same time. E.g. The following are two conflicting shots:

Shot (x,y,dx,dy, 5000,3000); Shot (x,y,dx,dy, 8000,5000);

2) In the game, there is a gap between two shots. You cannot shoot a bird immediately after one shot. The gap is around 5 seconds. So please adjust your t\_shot and ensure the gap between two shots more than 5000.

#### **Auto-Arrange mode**

We provide another convenient way for shooting, if you do not care about the exact time. We can arrange the shooting time for you. By setting the t\_shot field of each shot in the shot sequence to 0, the server will shoot the bird every 5 seconds. For example,

- 1) Shot (x,y,dx,dy, 0,3000);
- 2) Shot (x,y,dx,dy,0,5000);

The first shot will be made at time 0, and second shot will be made at time 5000. Besides, the first tap happens at time 3000 + 0 = 3000 and the second tap occurs at time 5000 + 5000 = 10000.

Note, if you want the server to arrange the shooting for you, you need to ensure **ALL** the t\_shot fields are set to 0 in a shooting sequence.

The server will treat the following conflicting shooting sequence in the self-manage mode

1) Shot (x, y, dx, dy, 0, 3000);

This work is licensed under Creative Commons Attribution-NonCommercial-ShareAlike 3.0 Unported License and can be accessed via https://github.com/aibirds/agent

- 2) Shot (x,y,dx,dy, 0,5000);
- 3) Shot (x,y,dx,dy, 10000,5000);

### **Focus Point**

The naive agent shoots a bird by first moving the mouse to the focus point (see Collect Trajectories), and then drag the bird to the release point, and release the mouse. A focus point is the middle of the top edge of the slingshot's bounding box. In automatic mode where the agent detects the focus point automatically, the right focus point depends on the correct detection of slingshot. Sometimes, the agent tries to execute shooting action, but the bird is not launched, it is likely due to the wrong setting of the focus point. To solve this, please set the focus point manually in **setup.ini** file by uncommenting # symbol in front of the entry focus\_point., and adjust the value manually according to the actual position of the point on the image. E.g.

"focus\_pt:274,528,1" means use (274,528) as the focus\_point in the level 1.

(In this case, the focus points is 175,408)

Then the agent will use the specified point as focus\_point in the corresponding level.

## **Compile using ANT**

You can use ANT to compile the source codes via command line. Ant is a Java library and command-line tool whose mission is to drive processes described in build files as targets and extension points dependent upon each other. To install ant, please refer to http://ant.apache.org/

ANT 1.7 or above required

To compile the source codes, go to the software directory, and use command

ant compile

To generate an executable file

ant jar
